

AUTO TICKETS CLASSIFICATION USING FLOW DESIGNER

Project Description:

Auto Tickets Classification Using Flow Designer is an automated ticket management solution designed to classify incoming support tickets based on their information and route them to the appropriate category or team.

The main purpose of this project is to reduce manual ticket classification and improve the efficiency of support operations. When a new ticket is created, the system processes the ticket information and uses a predefined Flow Designer workflow to identify the appropriate ticket category.

The solution can classify tickets based on information such as ticket description, issue type, priority and other relevant fields. After classification, the ticket can be assigned or routed according to the defined workflow.

Flow Designer provides a visual, low-code approach for designing and automating the ticket classification process. It allows different actions and conditions to be connected together to create an automated workflow.

The project helps organizations improve ticket handling, reduce repetitive manual work and provide a more structured support process.

Scenarios

Scenario 1: New Ticket Creation

A user creates a support ticket by providing the required ticket information. Once the ticket is submitted, the Flow Designer workflow is triggered automatically.

The workflow reads the available ticket information and begins the classification process.

Scenario 2: Ticket Classification

The Flow Designer checks the ticket information and identifies the appropriate category based on predefined conditions.

For example, tickets related to:

- Hardware
- Network
- Account
- Access
- Other support issues

can be classified into their respective categories.

Scenario 3: Ticket Assignment

After classification, the workflow can determine the appropriate assignment group or responsible team.

This reduces the need for support staff to manually review every ticket before assigning it.

Scenario 4: Priority Handling

The workflow can also use ticket priority information to determine how the ticket should be handled.

High-priority tickets can be identified and processed according to the organization's defined support workflow.

Technical Architecture

The project follows a workflow-based automation architecture.

Architecture Description

The user creates a ticket through the ticketing system.

The Flow Designer workflow is triggered when the ticket meets the configured trigger condition.

The workflow retrieves the required ticket information and evaluates predefined conditions.

Based on the result, the ticket category and other required fields can be updated automatically.

The classified ticket can then be routed to the appropriate assignment group or support team.

Technologies / Tools Used

Technology / Tool	Purpose
Flow Designer	Workflow automation
Ticketing Platform	Ticket creation and management
Workflow Actions	Processing ticket information
Conditions	Ticket classification
Business Rules / Logic	Classification decision making
Database	Storing ticket information
Web Interface	Ticket creation and monitoring

Pre-requisites

The following knowledge and requirements are useful for developing the project:

- Basic knowledge of ticket management systems
- Basic knowledge of workflow automation
- Understanding of Flow Designer
- Knowledge of triggers and actions
- Understanding of conditions
- Basic database concepts
- Basic knowledge of ticket fields
- Understanding of assignment groups
- Access to the required Flow Designer environment

Project Workflow

Milestone 1 – Requirement Analysis

The first milestone focuses on understanding the ticket management problem and identifying the requirements for automatic classification.

Activity 1.1 – Identify the Problem

Manual ticket classification requires support staff to review tickets and determine their category.

This can increase processing time when a large number of tickets are received.

Activity 1.2 – Define the Objective

The objective is to create an automated workflow that can classify tickets based on predefined rules.

Activity 1.3 – Identify Ticket Categories

The categories required for classification are identified according to the project requirements.

Example categories include:

- Hardware
- Software
- Network
- Account
- Access
- Other

Milestone 2 – Ticket Structure Design

This milestone focuses on identifying the information required from each ticket.

Activity 2.1 – Identify Ticket Fields

Important ticket fields may include:

- **Short Description**
- **Description**
- **Category**
- **Priority**
- **State**
- **Assignment Group**
- **Assigned User**

Activity 2.2 – Define Classification Rules

Rules are created to determine how a ticket should be classified.

For example:

If ticket contains Network-related information

Network Category

If ticket contains Software-related information

Software Category

If ticket contains Hardware-related information

Hardware Category

Milestone 3 – Flow Designer Configuration

This is the main development milestone of the project.

Activity 3.1 – Create Flow

A new flow is created in Flow Designer for automatic ticket classification.

The flow contains a trigger, actions and conditions.

Activity 3.2 – Configure Trigger

The trigger determines when the flow should start.

For example:

Trigger:

When a new ticket is created

The trigger automatically starts the workflow when the required ticket record is created.

Activity 3.3 – Get Ticket Information

The flow retrieves the required information from the ticket.

The information may include:

- Short Description
- Description
- Priority
- Category
- Other relevant ticket fields

Activity 3.4 – Add Conditions

Conditions are added to determine the appropriate classification.

Example:

Ticket Description

|

v

Check Keywords / Conditions

|

+---+---+---+

| | | |

v v v v

Hardware Software Network Other

Activity 3.5 – Update Ticket

After identifying the category, the workflow updates the ticket with the appropriate classification.

The workflow can also update other required fields such as assignment group or priority according to the configured requirements.

Milestone 4 – Automatic Ticket Classification

Activity 4.1 – Hardware Classification

If the ticket contains information related to hardware problems, the workflow classifies it as a hardware-related ticket.

Examples:

- Computer not working
- Keyboard problem
- Printer problem
- Monitor issue

Activity 4.2 – Software Classification

Software-related tickets can be classified automatically.

Examples:

- Application not opening
- Software installation issue
- Application error

- System software problem

Activity 4.3 – Network Classification

Network-related tickets can be identified based on the ticket information.

Examples:

- Internet connection problem
- Wi-Fi problem
- Network connection issue
- Server connectivity problem

Activity 4.4 – Account / Access Classification

Tickets related to accounts and access can be classified separately.

Examples:

- Password problem
- Login issue
- Account access
- Permission request

Activity 4.5 – Other Classification

If a ticket does not match the configured classification conditions, it can be assigned to a general or Other category for further review.

Milestone 5 – Ticket Assignment

After classification, the ticket can be routed to the appropriate support team.

Activity 5.1 – Identify Assignment Group

The workflow determines the assignment group based on the classified category.

Example:

Hardware

Hardware Support Team

Software

Software Support Team

Network

Network Support Team

Account

Access Support Team

Activity 5.2 – Update Assignment

The appropriate assignment information is updated automatically in the ticket.

This reduces manual assignment work.

Activity 5.3 – Ticket Status

The ticket status can be updated according to the workflow requirements.

Possible states include:

- New
- Assigned
- In Progress
- Resolved
- Closed

Milestone 6 – Testing

Testing is performed to verify that the Flow Designer workflow classifies tickets correctly.

Activity 6.1 – Hardware Ticket Testing

A sample hardware-related ticket is created.

Expected result:

Ticket → Hardware Category

Activity 6.2 – Software Ticket Testing

A software-related ticket is created.

Expected result:

Ticket → Software Category

Activity 6.3 – Network Ticket Testing

A network-related ticket is created.

Expected result:

Ticket → Network Category

Activity 6.4 – Account Ticket Testing

An account or access-related ticket is created.

Expected result:

Ticket → Account / Access Category

Activity 6.5 – Unknown Ticket Testing

A ticket that does not match any predefined condition is created.

Expected result:

Ticket → Other / General Category

Milestone 7 – Documentation

The complete project workflow, classification rules, Flow Designer configuration and testing results are documented.

The documentation includes:

- Project description
- Scenarios
- Architecture
- Requirements
- Workflow
- Classification rules
- Testing
- Results
- Conclusion

Exploring the Project Screens / Workflow

1. Ticket Creation

The user creates a new support ticket by entering the required information.

The ticket contains the issue details that are used by the classification workflow.

2. Ticket Details

The ticket details screen contains information such as:

- Ticket number
- Short description
- Description
- Priority
- Category
- Assignment
- Status

3. Flow Designer

The Flow Designer screen contains the automation workflow.

The workflow consists of:

Trigger

Get Ticket Information

Conditions

Classification

Update Ticket

Assignment

4. Classification Conditions

The condition section contains the rules used to identify the ticket category.

Each condition checks the ticket information and produces the required classification.

5. Classified Ticket

After the flow executes, the ticket displays the automatically selected category.

This allows support teams to identify the type of issue without manually classifying the ticket.

6. Assignment Group

After classification, the ticket can be assigned to the appropriate support group.

This creates a more organized ticket handling process.

Functional Features Overview

S.No	Feature Name	Feature Description	Module / Component	Status
1	Ticket Creation	Allows users to create support tickets	Ticket Module	Done
2	Ticket Information	Stores issue-related information	Ticket Module	Done
3	Flow Trigger	Starts the workflow automatically	Flow Designer	Done
4	Ticket Data Retrieval	Retrieves required ticket information	Flow Designer	Done
5	Classification Conditions	Checks ticket information	Flow Designer	Done

S.No	Feature Name	Feature Description	Module / Component	Status
6	Automatic Classification	Assigns a suitable ticket category	Classification Module	Done
7	Hardware Classification	Identifies hardware-related tickets	Classification Module	Done
8	Software Classification	Identifies software-related tickets	Classification Module	Done
9	Network Classification	Identifies network-related tickets	Classification Module	Done
10	Account Classification	Identifies account/access tickets	Classification Module	Done
11	Other Category	Handles unmatched tickets	Classification Module	Done
12	Assignment Group	Routes tickets to the required team	Assignment Module	Done
13	Ticket Update	Updates classified ticket information	Flow Designer	Done
14	Testing	Tests classification workflow	Testing Module	Done
15	Documentation	Documents the complete project	Documentation	Done

Benefits of the System

- Reduces manual ticket classification
- Saves support team time
- Provides consistent classification
- Improves ticket organization
- Automates repetitive tasks
- Helps route tickets to appropriate teams
- Provides a structured workflow
- Reduces classification errors caused by manual processing

Future Enhancements

The system can be enhanced with additional features such as:

- AI-based ticket classification
- Natural Language Processing
- Automatic priority prediction
- Sentiment analysis
- Automatic assignment to available agents
- Email notifications
- SLA-based ticket escalation
- Dashboard and reporting
- Classification accuracy monitoring

Conclusion

Auto Tickets Classification Using Flow Designer provides an automated approach for organizing and classifying support tickets.

The project uses Flow Designer to create a structured workflow that starts when a ticket is created, processes the ticket information, evaluates predefined conditions and automatically determines the appropriate classification.

The automated workflow reduces repetitive manual work and helps support teams organize incoming tickets more efficiently. The classified tickets can also be routed to appropriate assignment groups based on the configured workflow.

The project demonstrates how workflow automation can be used to improve ticket management and create a more structured support process. Future enhancements such as AI-based classification, automatic priority prediction, notifications and advanced reporting can further improve the system.
